WIND-TUNNEL INVESTIGATION OF AILERONS

ON A LOW-DRAG AIRFOIL

III - THE EFFECT OF TABS

By Ralph W. Holtzclaw and Robert M. Crane

Ames Aeronautical Laboratory
Moffett Field, California

WASHINGTON

NACA WARTIME REPORTS are reprints of papers originally issued to provide rapid distribution of advance research results to an authorized group requiring them for the war effort. They were previously held under a security status but are now unclassified. Some of these reports were not technically edited. All have been reproduced without change in order to expedite general distribution.

NACA ACR No. 4H15

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

ADVANCE CONFIDENTIAL REPORT

WIND-TUNNEL INVESTIGATION OF AILERONS

ON A LOW-DRAG AIRFOIL

III - THE EFFECT OF TABS

By Ralph W. Holtzclaw and Robert M. Crane

SUMMARY

An investigation was made of the effects of 0.30-aileron-chord tabs on an NACA 66,2-216 ($a = 0.6$) airfoil equipped with a 0.20-airfoil-chord plain sealed aileron. The aileron profiles considered consisted of one profile conforming to the normal NACA 66,2-216 ($a = 0.6$) ordinates and a profile consisting of straight-line surfaces from the trailing edge to the hinge-line ordinates of the aileron.

Basic data are presented from which the effect of tabs can be calculated for specific cases. The data are sufficient for the solution of problems of fixed tabs with a differential linkage, as well as simple and spring-linked balancing tabs.

INTRODUCTION

With every increase in size and speed of airplanes, the problem of attaining adequate lateral control without excessive control forces becomes less amenable to solution by simple aerodynamic balancing methods. Of the various methods of aerodynamic balance available, one of the most efficient is the sealed internal nose balance. However, sufficient lightness of control frequently cannot be attained by the use of an internal nose balance alone. The necessary balance may be so large that the required control-surface deflection cannot be obtained, or structural requirements of the main surfaces may be such that adequate

balance cannot be incorporated in the design. The aerodynamic effects of adjusting aileron hinge moments by alterations to the aileron profile by thinning and thickening the control surface have been shown in reference 1, and in reference 2 by thickening and beveling the control-surface trailing edge. Results of tests reported in references 3 to 5 have shown tabs to be an effective means of adjusting hinge-moment characteristics when used as fixed tabs in conjunction with a differential linkage, or as simple or spring-linked balancing tabs.

The purpose of the tests reported herein was to obtain quantitative data on the effect of tabs on the characteristics of ailerons on a low-drag airfoil in two-dimensional flow.

The tests were made in the 7- by 10-foot wind tunnel at Ames Aeronautical Laboratory.

COEFFICIENTS AND CORRECTIONS

The coefficients used in the presentation of results follow:

c_l airfoil section lift coefficient (l/qc)

c_m airfoil section pitching-moment coefficient (m/qc^2)

c_{ha} aileron section hinge-moment coefficient (h_a/qca^2)

c_{ht} tab section hinge-moment coefficient (h_t/qct^2)

P/q internal static pressure at aileron nose divided by dynamic pressure (fig. 1).

Δc_l increment of c_l due to deflecting the aileron from neutral

$\Delta P/q$ increment of pressure coefficient across aileron nose seal (pressure below seal minus pressure above seal divided by dynamic pressure)

where

- l airfoil section lift
- m airfoil section pitching moment about quarter chord of airfoil
- ha airfoil section hinge moment
- ht tab section hinge moment
- c chord of airfoil with surfaces neutral
- ca chord of aileron aft of aileron hinge line
- ct chord of tab aft of tab hinge line
- q dynamic pressure of air stream $\left(\frac{1}{2} \rho V^2\right)$
- V free-stream velocity

In addition to the preceding, the following symbols are employed:

- α_0 angle of attack for airfoil of infinite aspect ratio
- δ_a aileron deflection with respect to the airfoil
- δ_t tab deflection with respect to the aileron

The lift coefficients have been corrected for tunnel-wall effects. A comparison of force-test and pressure-distribution measurements of section lift coefficient and section pitching-moment coefficient indicated that the end plates had no effect on the coefficients with the surfaces neutral. No corrections have been applied to section hinge-moment coefficients and no end-plate correction has been applied to Δc_l . Because of possible tip losses, it is believed that the measured aileron effectiveness is slightly low and rates of roll computed from these data will be conservative. By comparison of these data with section data on a similar airfoil (reference 6), it is estimated that the decrease in the value of Δc_l due to this effect is not more than 12 percent.

MODEL AND APPARATUS

The airfoil was constructed of laminated mahogany to the NACA 66,2-216 ($a = 0.6$) profile of 4-foot chord and 5-foot span. The airfoil ordinates are given in table I. The ailerons were constructed of laminated mahogany and had a plain radius nose and a nose-gap seal of dental rubber dam. The aileron ordinates are given in table II. The ordinates of the normal-profile aileron are the same as the corresponding ordinates of the NACA 66,2-216 ($a = 0.6$) airfoil, and the ordinates of the straight-sided profile are the same as those of the straight-sided aileron of reference 1. The full-span tabs were constructed of steel in four sections to minimize the spanwise bending. The tabs had a radius nose and an unsealed nose gap of $0.0008c$. The ordinates of the tabs are the same as the corresponding ordinates of the ailerons. Details of the ailerons and tabs are shown in figures 1 and 2.

TEST INSTALLATION

The airfoil was mounted vertically in the test section of the AAL 7- by 10-foot wind tunnel No. 1 as shown in the photograph of figure 3. End plates were attached to the 5-foot-span section. Fairings of the same airfoil section as the wing were fastened to the tunnel floor and ceiling turntables and were used to shield the connections between the model and balance frame. These fairings were not equipped with ailerons. Provisions were made for changing the angle of attack and the aileron angle while the tunnel was in operation. Aileron and tab hinge moments were measured by means of electrical resistance-type strain gages which were mounted on members restraining the torque tubes of the surfaces from rotation.

TESTS

For each of the two aileron profiles, aileron characteristics were obtained at a Reynolds number of 9,000,000 for angles of attack of -4.13° , -2.06° , 0.01° , 2.07° , and 4.14° . These data covered a range of aileron angles of $\pm 20^\circ$ and a range of tab angles of $\pm 25^\circ$. Similar data were obtained at angles of attack of 8.27° and 12.37° at test Reynolds numbers

of 6,700,000 and 5,500,000, respectively. With the aileron neutral, section characteristics were obtained for tab deflections from -25° to 25° at a Reynolds number of 8,200,000.

RESULTS

The basic section data, with aileron and tab deflected and neutral, are presented in figures 4 to 11 for the normal-profile aileron and in figures 12 to 19 for the straight-sided profile aileron. These data may be utilized to predict the section characteristics of ailerons with internal nose balance by means of the equation

$$(c_h)_B = c_h + \Delta P/q \frac{(B^2 - R^2)}{2}$$

where

$(c_h)_B$ aileron section hinge-moment coefficient of aileron with sealed internal nose balance

c_h aileron section hinge-moment coefficient of plain sealed aileron

B nose balance (expressed as fraction of c_a)

R nose radius of plain aileron (expressed as fraction of c_a)

While the basic data are useful for purposes of design, the prediction and comparison of the effects of tabs may be conveniently demonstrated by means of section parameters. These section parameters as taken from the data contained herein are summarized in table III.
